Public Data and Visualizations: How are Many Eyes and Tableau Public Used for Collaborative Analytics?

Kristi Morton, Magdalena Balazinska, Dan Grossman, Robert Kosara, and Jock Mackinlay

University of Washington, UNC Charlotte, Tableau Software

ABSTRACT

Recently, online visual analytics systems have emerged as popular tools for data analysis and sharing. The database community has an important role to play in shaping the design and implementation of these new types of systems. Little, however, is known about how these systems are used today. In this paper, we address this shortcoming by presenting an analysis of usage patterns of Many Eyes and Tableau Public, two popular Web-based, collaborative visual analytics systems.

1. INTRODUCTION

As data has become more publicly available on the Web, for example, through local and national government initiatives such as the Open Data movement [6], a broader audience has emerged as data consumers and knowledge-seekers (referred to as data enthusiasts) [11]. These people are not statisticians or programmers, yet want to use data to answer a question or solve a problem. A typical example is a news reporter who wants to use data and visualizations to illustrate a story and make it available online (e.g., on her blog).

Over the past few years, increasingly many online data visualization systems have appeared to meet the demands of such users for data analysis and sharing [2, 1, 4, 18, 5, 9, 10]. The core functionality of these systems is threefold: (1) They enable users to visually explore their data: users have access to a graphical user interface through which they can easily create various charts and graphs. Importantly, through these interfaces, users are basically executing queries to filter, group by, and aggregate datasets. (2) These systems also facilitate the integration and study of multiple datasets. (3) Finally, they support collaboration between users through sharing visualizations and data online for both viewing and editing by others [12, 20]. These services are thus a new type of easy-to-use data management and analytics systems.

While different systems have different architectures, several are based on the integration of a visualization front-end with a database management system back-end [19, 9]. For example, Tableau supports analysis across a variety of structured, heterogeneous data sources (e.g., delimited text files, cubes, data marts, and databases), and issues live queries to these sources to obtain the necessary data to render each visualization. With live query support, interactive analysis is possible: visualizations can be altered on-the-fly and multiple data sources can be joined together.

Unlike Tableau Public, Many Eyes visualizations are created and published through a Web browser. Either structured (i.e., tables) or unstructured (i.e., bag of words) data is ingested through a browser using cut-and-paste operations from a text file up to 5 MB in size. Once a visualization is chosen for a given data set it cannot be arbitrarily altered nor combined with other data. Moreover, while both systems share many of the same visualization types (i.e., bar, line, text, pie, area, scatter, and maps), Many Eyes includes a number of unique text analysis techniques that are not available in other systems. Such visualizations include word clouds, phrase nets, and word trees.

Despite their growing popularity, little is known about how these systems are being used. Even basic statistics such as the number of users are often not published (e.g., Fusion Tables [9]), let alone any details of user activity. The most prominent system, Many Eyes, started in early 2007, and initial studies [8] indicated a significant uptake, as well as collaboration between users; but there have been no follow-up studies on usage, nor have there been comparable studies of other web-based or web-centric visual data analysis systems. Shortly before Many Eyes, in December 2006, Swivel.com was launched. Swivel was much simpler and less academically ambitious than Many Eyes, but run as a start-up rather than an experiment. It shut down in summer 2010, casting doubt on whether there was a market for web-based visual data analysis systems. Shortly before Many Eyes, in December 2006, Swivel.com was launched. Swivel was much simpler and less academically ambitious than Many Eyes, but run as a start-up rather than an experiment. It shut down in summer 2010, casting doubt on whether there was a market for web-based visual data analysis systems. At the same time, there is clearly broad interest in data integration, analysis, and visualization. The New York Times, The Washington Post, The Guardian, and other news media are not only increasingly using visual data analysis as part
and all of the specific VizQL\(^1\) definitions [17] that produce each visualization. For Many Eyes, metadata was collected from the visualization types used and inferred from data sets uploaded.

3. RESULTS

We present the key results of our analysis, organized around our four core questions related to the user-base, collaborations, single-dataset analytics, and analytics of integrated datasets.

### 3.1 User-base

The first question that we ask is whether web-based visual analytics systems are at all popular. To answer this question, we measure the size of the user-base for each system. Figure 1 shows how the systems are growing over time in terms of the number of opened accounts. As the figure shows, since its inception in January 2007, Many Eyes, has grown to over 46,000 authors who have published over 358,000 data sources and more than 149,000 visualizations. For Tableau Public, its user-base includes 24,500 authors who have contributed over 73,000 workbooks, 107,500 datasets, and 269,000 visualizations (Table 1). We define authors to be users who have published at least one data set or visualization. These systems thus have moderate numbers of users today, but their popularity is continuing to grow significantly each year.

The natural next question is how active are these authors over time. Interestingly, as Table 2 shows, half the users (or almost half) are one-time users who publish only one dataset or visualization. The remaining users are mostly light users who publish two to four

\(^1\)Visual Query Language (VizQL) a formal declarative language for describing visualizations.
visualizations. Only 10% to 17% are prolific users who publish five or more data sets or visualizations.

Despite the significant age difference between the two systems, it is still interesting to note the most prolific author who is not directly affiliated with either system: on Many Eyes such a user contributed 1,617 data sets and visualizations; and on Tableau Public 2,927 data sets and visualizations were published by one user. Since the majority of users are one-time or light users, does it mean that most of the activity in the systems is due to novices? Figure 2 confirms this hypothesis. In the figure, we group users into cohorts based on the quarter in which they publish their first visualization (workbook on Tableau Public). For each quarter, the figure shows the fraction of active accounts that come from each returning cohort. For example, in the third quarter, 8% of active accounts in Many Eyes belong to the second cohort and 11% of active accounts belong to the first cohort. The remaining 81% active accounts (not shown) belong to users who joined the system that quarter. On average only 17% of active accounts in Many Eyes belong to returning users from any cohort. The average is 31% for Tableau Public. Hence, web-based data analysis systems today need to provide good support for novices.

One hypothesis for high user churn is bad system performance. According to a study published on Web users’ tolerable waiting time [15], two seconds is considered an acceptable waiting time for loading Web pages. We measure, however, that 84% of all visualizations on Tableau Public take less than two seconds to load (includes both query and rendering time) and 98% are under ten seconds (the accepted limit for keeping a user’s attention focused on a given task [14]). Although attitudes and expectations change over time, the basic capability of human attention has not changed over the decades [7, 14]. Thus, our results indicate that the majority of load times should not negatively impact Tableau Public’s users. Performance alone thus cannot explain the high degree of user churn. It could, however, simply be that the systems do not offer the visualization capabilities users want (e.g., limited to no support for unstructured data). Users explore the systems but walk away when they find them unsuitable for their needs.

If we frame these retention results in the context of other free, web-based services such as Twitter, we see that low retention after initial use is common. According to a 2009 Nielsen report [13] only 40% of Twitter users returned to use the site after the first month.

**Bottom Line:** Web-based visual analytics systems continue to attract thousands of users, but most of them use these systems lightly right after registering and then stop. Only a small fraction of users grows into power users. The implication for the database community is that Web-based visual analytics systems must be geared toward supporting novice users and there is significant room for improvement in retaining these users.

### 3.2 User Interaction and Collaboration

Since both systems are designed for sharing visualizations and collaboratively analyzing data, we explore the frequency of viewership, collaboration, and sharing in this section.

#### 3.2.1 Viewership

Based on a distinct count of user cookies, we found that there are approximately 52 million unique visitors to Tableau Public. **Visitors are thus several orders of magnitude more numerous than the authors** (only ≈ 24,500 authors). Additionally, we found that the top 50% of all Tableau Public traffic is attributed to 244 distinct workbooks (or 0.3% of all workbooks). For Many Eyes, however, we did not have access to the equivalent traffic and viewership information.

#### 3.2.2 Collaboration

On Tableau Public and Many Eyes, users can download, edit, and republish any visualization and supporting data set. To get a sense of the degree of such collaborative activities among authors, we explore how often authors take existing content and evolve it for their own analytical needs (e.g., by changing the visualization content to explore some other dimension or measure) and then republish it with their insights. In our approach, we trace the provenance of Tableau Public workbooks that were created by one author and edited and republished by a different author (called a derivation). Figure 3(top) shows that a workbook is about five times more likely to be derived if it is not the author’s first publication. Nevertheless, the probability of derivation remains small at 0.6%. Very few workbooks are derived more than once. Only 28 workbooks were derived > 4 times.

In Figure 3(bottom) we observe two types of collaborative behaviors. Some workbooks are derived multiple times by alternating between the same two authors as in a **Direct Collaboration** while others are derived by a di-

Figure 2: Many Eyes (left) and Tableau Public (right) author cohorts for the first 12 quarters (3 years). Authors are grouped into cohorts based on the quarter in which they published their first visualization or workbook. The fraction of authors that returned to the site to publish a dataset or visualization is shown as the percent of accounts still active for each quarter.

Figure 3: Derived Tableau Public workbooks partitioned by publication time (top) and nature of collaboration (bottom).

different author each time as in an Indirect Collaboration.

No equivalent derivation information is available for Many Eyes. However, in order to get a sense of the degree of influence one author’s contributions have on other authors, we measure how often authors reuse data uploaded and shared by others for their visual analysis in Many Eyes. We find that only 6% of datasets are used by multiple authors, which is consistent with Tableau’s workbook derivation statistics, and that 20% of datasets are used in multiple visualizations. We cannot compute this statistic for Tableau Public because published workbooks make a copy of the data being visualized.

3.2.3 New Content Published: Data Types

We next consider what are the predominant data types that are being visualized in both systems. First, in Figure 4(a), we see that Number (51%) and String (44%) are the most common data types in visualizations on Tableau Public. It is interesting that their use is fairly balanced, while intuition would indicate that numbers might be more common due to the quantitative nature of business analytics. The Number data type includes both integers and reals. Finally, we see fewer specialized types such as Datetime and Date, which indicates that visualizations of time-based data are less prevalent.

Many Eyes, however, has a skewed distribution of String/Categorical types. In Figure 4(b), we see that 91% of columns on Many Eyes are of this type. This finding is consistent with Many Eyes’s greater emphasis on text-based visualizations (i.e., word clouds, phrase nets, and word trees) that are not available elsewhere.

Bottom Line: Online visual analytics systems are read-heavy today: Orders of magnitude more people are viewers compared to authors. Additionally, as is typically the case for database access patterns, viewership is skewed toward a small fraction of hot visualizations. Interestingly, while publishing visualizations is common, collaborations among users remain infrequent. Incentivizing and supporting collaborations thus remain critical challenges for these systems.

3.3 Single-Dataset Analytics

Today’s online visual analytics systems are designed for small data. Most of these systems put a bound on the size of datasets that can be processed. On Many Eyes, data sizes are limited to 5MB, while on Tableau Public, each user gets a 50MB account and a visualization can operate on at most 100,000 rows. Interestingly, we find
that 90% of user accounts in Tableau Public use less than half of their 50MB quotas. Hence most users do not push the pre-set limit. The focus on small-size datasets affects the size of the visualized relations as shown in Table 3: the majority of visualized relations stays well below the pre-set cap of 100K rows.

Tableau Public also offers a paid (a.k.a., Premium) tier, which allows accounts to go beyond the 100,000 rows limit. These accounts (along with some accounts on Many Eyes) visualize more than an order of magnitude more data, which seems to imply the need for the online visualization of bigger data too.

Interestingly, datasets in both systems contain on average a large number of attributes, especially in Tableau Public, where the median dataset has 20 attributes and the top 10% have more than 100 attributes. Only a small fraction of these attributes, however, is visualized simultaneously as shown in Figure 5: 52% of visualizations with a single data source use at most 3 columns and 90% use at most 6. A similar trend appears for visualizations over integrated data sources as we discuss further in Section 3.4. The figure shows results for Tableau Public. No equivalent information was available for Many Eyes.

Table 4 shows the breakdown of the most common visualization types used for a given number of columns. The values denoted with a ‘*’ in Table 4 show that a second visualization type was within 5% from the top choice for that given number of columns. For single data sources, we see that the text table is the most common type when there is only one data column present in the visualization. As the number of columns increases, we see a shift in visualization techniques used: bar views become the dominant technique for 2–4 columns and maps are the most popular for 5–8 columns. This behavior is not too surprising since map views always include two virtual columns that represent the latitude and longitude coordinates.

**Bottom Line:** Most visualizations have modest data sizes, well below the limits set in existing systems although some users with special privileges visualize datasets with more than one million rows. Visualizations also focus on a small number of attributes at any one time, even though many more attributes are available. Finally, as the number of columns used increases, so does the complexity of the visualization type (e.g., maps require more columns than other types like bar views.)

### 3.4 Integrating Multiple Data Sets

In this section, we study the trends in data and visualization on Tableau Public in the context of data integration from multiple data sources. We omit Many Eyes from this section because the platform currently does not support data integration.

#### 3.4.1 Semantic Entities for Data Integration

On Tableau Public, there are 5,532 visualizations that were created by joining multiple data sets. Of these visualizations, we ask how do authors combine data sets for their analysis? To answer this question we manually categorized all of the join keys for the 5,532 visualizations (2%) that have integrated data to get a sense of the most popular semantic entities. This process entailed inspecting the column name, data type, and data values of each join key. In the case where the column name was in a foreign language, we used Google Translate on the name and (in some cases) values of that column. If we were still unsure, we opened the workbook to inspect the visualization that was associated with that join key. Figure 6 summarizes the semantic entities of the join keys in five different categories: people, places, time, objects, and other. The people category contains any information pertaining to people, including names and demographics. The places category is restricted to
4. CONCLUSIONS

We studied four primary dimensions of two popular online visual analytics systems: (1) what types of users are leveraging these systems and how heavily, (2) how are users collaborating and interacting with the published content, (3) how do users analyze a single-dataset and (4) how they integrate data sources. We find that web-based visual analytics systems have much room for growth: they attract large numbers of users but most users do not push the limit of what these tools can do.
