

# Randomized Algorithms

- Algorithms that make random choices during the computation
- Often faster, simpler than traditional algorithms

# Miller-Rabin primality test

**Input:**  $n$ -bit number  $x$ .

**Goal:** decide whether  $x$  is a prime number or not.

- Extremely important problem: many applications in cryptography.
- There is a deterministic polynomial time algorithm (AKS-2000), running time is  $O(n^{12})$

**Miller-Rabin primality test (running time  $O(n^2)$ ):**

1. Express  $x - 1 = 2^s \cdot d$ , where  $d$  is odd.
2. Pick  $a \in \{1, 2, \dots, x - 1\}$  uniformly at random.
3. If for some  $t = 1, 2, \dots, s$ ,  $a^{2^t \cdot d} = 1 \pmod{x}$ , yet  $a^{2^{t-1} \cdot d} \not\equiv -1 \pmod{x}$ , conclude that  $x$  is not prime. Otherwise conclude that  $x$  is prime.

**Theorem:** If  $x$  is prime, the test concludes that  $x$  is prime with probability 1. If  $x$  is not prime, the test concludes not prime with probability at least  $3/4$ .

# Min-Cut

**Input:** An undirected graph.

**Goal:** Partition the vertices of the graph in two sets  $A, B$ , to minimize the number of edges going from  $A$  to  $B$ .

- You can use flows and cuts, but there is a simpler randomized algorithm

## Karger's Algorithm:

1. In each step, pick a uniformly random edge and contract it.
2. Stop when you have just two vertices.
3. Output the corresponding cut.

## Karger's Algorithm:

1. In each step, pick a uniformly random edge and contract it.
2. Stop when you have just two vertices.
3. Output the corresponding cut.

**Thm:** The algorithm finds the min-cut with probability at least  $2/(n(n-1))$ .

**Pf:**

- Suppose the min-cut cuts  $k$  edges.
- Then every vertex must degree  $\geq k$ , or else that vertex would already give a smaller min-cut.
- So, the number of edges in the graph is at least  $nk/2$ .
- The probability we pick one of the edges of the min-cut is at most  $k/(nk/2) = 2/n$ .
- The probability that an edge of the min-cut is never picked is at least  $(1 - 2/n)(1 - 2/(n-1)) \dots (1 - 2/3)$   
 $= ((n-2)/n) \cdot ((n-3)/(n-1)) \cdot ((n-4)/(n-2)) \dots = 2/(n(n-1))$ .

## Karger's Algorithm:

1. In each step, pick a uniformly random edge and contract it.
2. Stop when you have just two vertices.
3. Output the corresponding cut.

**Final algorithm:** Repeat the above algorithm  $100n(n - 1)$  times. Output the best cut that you find.

# Graph coloring

**Input:** An undirected graph.

**Goal:** Find a 3-coloring of vertices that maximizes the number of edges that get 2 colors.

**Algorithm:**

Randomly color the vertices of the graph red, blue, green.

**Thm:** The expected number of edges that are properly colored is at least  $2m/3$ .

Pf: For each edge  $e$ , define  $X_e = 1$  if the edge  $e$  gets two colors, and  $X_e = 0$  otherwise.

$$\mathbb{E}[X_e] = \Pr[X_e = 1] \cdot 1 = 2/3.$$

So, by linearity of expectation,

$$\mathbb{E}\left[\sum_e X_e\right] = \sum_e \mathbb{E}[X_e] = 2m/3.$$

**No known poly time algorithm achieves  $> 2m/3$ .**

# Dominating set

**Input:** An undirected graph, every vertex has degree  $\geq \Delta$ .

**Goal:** Find a small set of vertices  $S$  such that every vertex is either in  $S$  or is a neighbor of  $S$ .

## Algorithm:

1. Randomly include each vertex in the set  $X$ , with probability  $p$ .
2. Let  $Y$  be the set vertices not in  $X$  and not a neighbor of  $X$ .
3. Output  $X \cup Y$ .

**Claim:** The expected size of  $X \cup Y$  is at most  $pn + n(1 - p)^{1+\Delta} \leq pn + e^{-p(1+\Delta)}n$ .  
Set  $p = \ln(1 + \Delta)/(1 + \Delta)$ , to get expected size at most  $n(1 + \ln(1 + \Delta))/(1 + \Delta)$ .

## Pf of Claim:

1. The expected size of  $X$  is  $pn$ .
2. For each vertex, the probability that it is included in  $Y$  is at most  $(1 - p)^{1+\Delta}$ .
3. So the expected size of  $Y$  is  $n(1 - p)^{1+\Delta}$ .

# Matrix product checking in $O(n^2)$ time.

**Input:**  $n \times n$  matrices  $A, B, C$

**Goal:** Check that  $AB = C$

**Algorithm:**

1. Pick  $x \in \{0,1\}^n$  uniformly at random.
2. Check  $ABx = Cx$

**Claim:** If  $AB \neq C$ , then  $\Pr[ABx = Cx] \leq 1/2$ .

**Pf of Claim:**

Let  $D = (AB - C)$

Suppose  $D_{i,j} \neq 0$ , then  $(Dx)_i = \sum_k D_{i,k}x_k = D_{i,j}x_j + \sum_{k \neq j} D_{i,k}x_k$ , so for every fixing of  $\sum_{k \neq j} D_{i,k}x_k$ , the probability that  $(Dx)_i = 0$  is at most  $1/2$ .
